FORTRA

GUIDE (Agari)

Fortra Email Security + Microsoft 365

Next-Generation Security for Cloud-Based Email

Email is undergoing a fundamental transformation as organizations worldwide shift more office productivity and business applications to the cloud. With over 63 million subscribers according to their recent annual Shareholders' meeting, Microsoft 365 arguably leads this movement.

But for all of its convenience and utility, email has always been highly vulnerable to cyberattacks on multiple fronts, providing fertile grounds for the global email security market to record CAGR growth rate of 9.9%, putting it on track to reach US \$3.93B in 2023.¹ Organizations are spending billions to secure their email, but is all that money being invested wisely?

The secure email gateway (SEG) represents a sizable chunk of that spend. Unfortunately, the SEG is no match for modern identity-based attacks that easily evade signature-based detection. As a point of proof—according to Egress' Insider Data Breach Survey from 2021, 73% of organizations suffered serious breaches caused by phishing,² not to mention countless fraud losses from schemes, including executive and vendor impersonation, ransomware, and account takeovers.

Recognizing that email security is an organizational priority, about 60% of large organizations put comprehensive security awareness training in place by 2022.³ But, as security training becomes the norm, SOC teams already dealing with an overall cybersecurity skills shortage are becoming inundated with employee-reported phishing incidents—of which around 68% globally are ultimately determined to be false positives.⁴

The global email security market will record CAGR growth rate of 9.9%, putting it on track to reach US \$3.93B in 2023. As they migrate to M365, more organizations are recognizing that current investments in email security and phishing response deserve a closer look. While legacy email security vendors continue to shore up the secure email gateway and the financial annuity it represents to them, more organizations are embracing the reality that current email security architectures are fundamentally inadequate.

Cloud-first organizations are ditching the SEG and taking advantage of the enriched security features in M365 and the new Fortra Email Security architecture, a combined solution designed to stop malicious email attacks that often come without malware or other recognizable payloads. They have found that the SEG impedes the native security controls of M365 by obscuring the email header and feedback loop. By removing the SEG, they have improved security, reduced costs and enabled business agility.

This new approach blocks not only traditional spam, virus, and malware, but also the next generation of identity deception attacks. It secures the corporate sending domain from unauthorized use. And, in a significant departure from legacy security controls, it detects threats moving laterally across the organization and remediates newly identified threats that have made it to the inbox by evading initial detection or that weaponized post-delivery.

More organizations are embracing the reality that current email security architectures are fundamentally inadequate.

Introduction to a Cloud-First World

The Migration of Workloads and Security to the Cloud

When Marc Benioff launched the "no software" movement on the eve of the dot-com bust in 1999, there was little indication of the tectonic shift to come across the business IT landscape.

While "Googled" became a word, "elastic cloud" compute and storage became the norm and organizations turned to Infrastructure-as-a-Service (IaaS) as prices for cloud hosting dropped precipitously. Organizations worldwide could now place workers and facilities just about anywhere around the globe and adjust IT strategy and workloads on the fly.

Platform-as-a-Service (PaaS) has since emerged as a compelling way to free organizations from decades of layered on-premises systems, improve security, and deliver integrated services.

As the dust began to settle, what started off as an ingenious way to eliminate IT capital expenditures, alleviate overhead, and accelerate software deployment morphed into a new way of business.

laaS, PaaS and Software-as-a-Service (SaaS) turned out to be ideal enablers for an increasingly virtual and mobile workforce. Equipped with the ability to avoid up-front time and cost and to quickly phase out inefficient services, business agility improved.

In 2022, global IT spending for cloud technologies topped \$3.6 trillion.⁵

Perhaps no SaaS solution illustrates this better than M365, which didn't just move to the cloud, but also reinvented the office productivity suite and became more resilient to cyber attacks. Now, there are compelling business reasons to move email security to the cloud as well.

Examining Efficacy and Risk of Traditional Email Security Controls

Persistent Security Gaps in Legacy Systems

Given the substantial investments in email security infrastructure over the past few decades, the current state of email security is surprisingly dismal.

As of January 2023, 3.4 billion phishing emails are sent daily, and the annual number goes way beyond one trillion.⁶ Many of these result in a data breach, which cost approximately \$4.65 million per attack, not to mention the long-term damage to brand reputation and regulatory fines.⁷

Executive spoofing has become commonplace because the core email architecture allows end users (instead of the network) to specify the sending identity. Currently, 2 in 3 Fortune 500 companies still remained vulnerable to getting impersonated in phishing scams targeting their customers, partners, investors, and the general public.⁸

Even with domains protected, workers can be attacked through techniques such as display name deception and look-alike domains. Emailbased scams utilizing these techniques can lead to email account takeover (ATO), which allows cybercriminals to pose as the individual to divert money, steal information, and perform other malicious activities. Making matters worse, new single sign-on (SSO) capabilities can exacerbate the incident, leaving sensitive documents, confidential information, and collaboration tools exposed to unauthorized access.

ATO-based attacks are especially dangerous because they are notoriously difficult to detect and serve as a gateway to lateral movement as threat actors glean important context to compromise additional accounts, escalate their privileges, and gain access to other systems,

all of which can result in a data breach across the extended enterprise. We explore a particularly virulent attack modality called vendor email compromise (VEC) in our recent <u>Silent Starling threat dossier</u>.

Malware, virus, and Trojan attacks are still commonplace, but with effective defenses having moved into M365, attacks have shifted from targeting network and infrastructure to targeting core human emotions of fear, curiosity, and anxiety. These social engineering attacks come without a recognizable payload, so they typically bypass the SEG with plain-text emails that do not utilize the traditional techniques of malicious URLs and attachments.

For its part, the SEG checks incoming email only on receipt and generally does not re-check the inbox for latent threats that evaded detection or that weaponized post-delivery. The legacy protection also only protects against external attacks as email flows into the organization, completely ignoring the email flowing across the organization.

Moving Email Security Forward

The Business Imperative for a Modern Security Architecture

To supplement the protection of the SEG, organizations have turned en masse to phishing simulation training. Currently around 98% of organizations use phishing simulation to train employees.⁶ But the math is against them.

And SOC teams are already dealing with a widespread cyber skills shortage and since the abundance of advanced email attacks have increased substantially and exploits can take months to detect, they simply can't keep up with continuous monitoring of all the threats reported.

While phishing training can help, it is hard to definitively measure its effectiveness. Unfortunately, it takes only one successful attack to do serious damage. It turns out that aside from the organizational drag that comes from mass distrust of the inbox, putting employees in the direct line of defense against email-based cyber attacks is a somewhat risky proposition, particularly given the existential threats a major breach can represent.

But as ineffective as the SEG tends to be against advanced email attacks, it also presents a significant obstacle to cloud-first strategies. By placing the SEG "inline" as email passes through, the SEG obfuscates the native security features of Exchange Online Protection, preventing M365 from optimal function. It changes the email header information viewable by M365 and the feedback loop from users goes directly to the SEG, leaving M365 none the wiser from user-reported phishing attempts.

All the while, the SEG requires maintenance, training, and support that consumes valuable SOC team resources. Taken together, the cost and overhead of the SEG, the systemic risks to the business plan from attacks that evade it, and the negative impact it has on native security controls built into M365, the SEG represents a significant hindrance to organizations looking to drive higher labor productivity and worker output.

This, of course, is a big part of the reason organizations adopt M365 in the first place and typically as part of their digital transformation strategies. Simplifying IT infrastructure while providing workers new and improved ways to communicate, collaborate, and perform their job functions both safely and securely is a critical objective for oganizations looking to attract and retain the best talent as the new generations—the digital natives— enter the workforce.

And while M365 provides a level of security closely resembling what organizations would find in a traditional SEG, including the ability to detonate and identify actively malicious payloads with Microsoft Phishing Defense[™], additional protections against the most dangerous threats are needed to safeguard the organization from advanced threats, such as business email compromise, executive spoofing, and account takeovers.

The New Paradigm for Email Security

Cloud-Based Security for a Cloud-First World

An evolution of the legacy secure email gateway, the next-generation Fortra Email Security is purposefully built for the cloud-first world and differs in several remarkable ways. Because it's a cloud-native SaaS application and compliments the built-in security features of M365, it offers several key enhancements.

Many of the legacy features of the SEG are already pre-built into M365 via Exchange Online Protection (EOP) and the optional Phishing Defense. In fact, M365 provides support for all areas that have been traditionally protected by the SEG: pre-content filter based control, integrated antispam, integrated antivirus, attachment sandboxing, URL analysis, and data loss prevention.

Designed to assess incoming emails by analyzing content and infrastructure reputation, these platform-native controls are proving essential to ferreting out spam, malicious URLs and malware, certain keywords, or a high volume of attacks from a single IP. In fact, according to a recent Gartner report, anti-malware and anti-spam features built into M365 are now being recognized as best in class.⁹

For those areas not fully protected by native functionality, the M365 architecture offers APIs such as the Microsoft Security Graph that enable complementary security solutions to integrate seamlessly. This is where many organizations enable the secure email gateway, but because SEGs were designed two decades ago, their architecture nearly always requires that it be inline in the mail flow, slowing down mail delivery and introducing a point of failure. Beyond the mail deliverability and increased risk of downtime, inline SEG architecture actually hinders the effectiveness of the M365 security by modifying header data before it reaches Exchange Online Protection or Phishing Defense.

Unfortunately, cybercriminals rely on finding new and innovative ways to bypass the filters organizations put into place to protect against them, which is why they have recently turned to identity-based deception. Different from traditional email attacks, this next-generation of email attacks rely on impersonation and plain-text emails to bypass the filters set against the attacks of the past.

This is where Fortra Email Security augments the controls set by Exchange Online Protection to prevent advanced attacks on M365 environments. Designed specifically to identify when a message is malicious based on identity and models of trusted behavior rather than content, Fortra's Cloud Email Protection prevents the most dangerous types of attacks from ever reaching user inboxes. And for those emails that evade initial detection or weaponize after delivery, Fortra's Suspicious Email Analysis provides options to automatically remove emails from user inboxes, effectively preventing users from opening the email or clicking on malicious links.

Using Artificial Intelligence to Protect Email

Malicious emails that use identity deception continue to bypass the legacy SEG and the native controls of M365 because they are notoriously difficult to detect. Consisting of only a few words, emails reach the targeted end user because there is no malicious content to identify. Those security systems looking for previously recognized signatures of malicious content can find nothing wrong with the email. Once the email passes through security to the inbox, the scam becomes easy to perpetuate. Cybercriminals count on the human emotions of fear, curiosity, and anxiety to convince the recipient to reply. Once engaged in a conversation, the scammer simply needs to ask for a wire transfer, gift card purchase, or payroll diversion to complete their scam.

Fortra's Data Science team employs a combination of machine learning, large language models, and neural networks to determine whether an email should be trusted. It quickly detects and stops advanced impersonation threats, like BEC, that bypass signature or patternbased defenses, before reaching user inboxes. In contrast, M365 is generally not able to detect malicious emails that use impersonation techniques. As such, these malicious emails continue to bypass the native controls of M365 because they look for previously recognized signatures of malicious content and thus can find nothing wrong with the emails. And any such detection requires cumbersome rule configuration and upkeep from M365. This new approach gets more effective with every email analyzed. As a result, it effectively transitions the email security paradigm from one that was designed to address isolated events to one that continuously protects the organization against evolving email threats, as quickly as they emerge. And because this technology is always on, it becomes possible to continuously rescore messages and remove those that evaded initial detection from inboxes.

So while M365 stops the vast majority of the most common types of attacks, Fortra provides the defense needed to stop the most dangerous and sophisticated attacks. With this combination of Fortra Email Security and M365, email attacks are stopped with 99.9% efficacy—enabling users to trust their inbox and SOC teams to quickly and efficiently identify and respond to emerging threats.

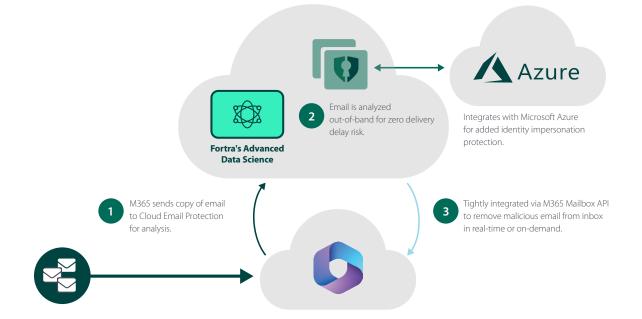

Microsoft 365 + Fortra Email Security

The Next Generation of Advanced Protection for Cloud-Based Email

The next-generation approach to email security protects against new and advanced attacks better than its predecessors, but it also encompasses additional features not typically present in a SEG. With the ability to authenticate legitimate sender domains, inspect email flowing laterally across the organization, and recheck the inbox to detect and remediate latent threats, the next-generation of email security is designed for modern organizations undergoing a digital transformation.

In either a cloud-only or hybrid environment, Fortra Email Security uses secure APIs to ensure faster mail delivery and prevent downtime. This ensures that the native M365 security controls are not blinded by a legacy inline SEG architecture.

This represents a significant departure from simply tacking on additional products and feature sets to the traditional SEG in what can best be described as a band-aid approach. Instead Fortra's comprehensive solutions transform email security from a tactical, event-based approach to a strategic, <u>continuous process</u> that learns from evolving threats to block 99.9% of all advanced attacks and helps SOC teams reduce detection and remediation time by up to 95%.³

Advanced Email Security Coverage Charts

Fortra Email Security, Microsoft 365, and Combined Solutions

To protect corporate domains from being spoofed, Fortra provides <u>DMARC email authentication</u> and helps organizations manage all third-party senders to reach enforcement at p=reject as quickly as possible. This prevents unauthenticated emails from reaching the inboxes of customers, partners, and employees.

This first step in securing the email environment provides the minimum level of protection to prevent brand abuse and stop cybercriminals from tricking unsuspecting customers and employees. In fact, Microsoft itself uses Agari DMARC Protection to protect its domains such as microsoft.com, outlook.com, and office365.com.

For the business email compromise scams and account takeover-based threats that use display name deception or look-alike domains, Fortra Email Security augments the Microsoft security controls to catch additional identity deception-based threats. Using a highlyinnovative identity graph to model trust relationships, Fortra's Advanced Data Science detects malicious emails by understanding identities and relationships between sender and recipient. In this way, our solution can adjust to evolving threats and prevent them from reaching inboxes.

And unlike other systems, our solution not only protects against emails coming into the organization (AKA north-south traffic), but also monitors and secures the emails traveling within an organization from employee to employee (AKA east-west traffic) to quickly discover if an internal account has been compromised. Part of the integrated solution for preventing advanced attacks, this key capability protects against bogus employee-to-employee emails.

Taking email security one step further, Fortra Email Security works directly with M365 to continuously monitor all inboxes within an organization, detecting latent threats as soon as new threat intelligence is discovered. For phishing incidents that need closer inspection, <u>Fortra's Continuous Detection & Response</u> helps prioritize, triage, investigate and remediate threats in a matter of minutes, so cybercriminals never have the opportunity to redirect money or exfiltrate data. This has been shown to decrease phishing response time by up to 95%.

Combining Fortra Email Security with M365 provides next-generation security to protect against new and evolving email attacks and security issues while simultaneously eliminating the need for legacy infrastructure. As cybercriminals become more adept and discover new attack tactics, Microsoft and Fortra continue to work together to protect your inbox from evolving threats—increasing confidence in your email ecosystem and saving you time and money.

Conclusion

Moving into the Next Generation of Email Security

After almost five decades in use, the architecture supporting enterprise email has been fundamentally redesigned and moved to the cloud. M365 sits at the forefront of this movement.

In turn, the legacy Secure Email Gateway has been commoditized, with key signature-based defenses moving into M365. Fortra Email Security augments these native security controls to protect against modern, identity-based attacks.

Fortra Email Security works with Exchange Online Protection and Microsoft Defender—not against them—to prevent business email compromise, domain spoofing, spear phishing, account takeovers, and all forms of identity-based email attacks.

M365 and the Fortra Email Security solutions are proven to work together to help organizations stay safe, reduce phishing incident investigative workloads, and provide premium protection of their email environment so employees, partners, and customers can trust their inboxes.

Organizations that have moved to M365, as well as those with hybrid deployments, can rely on the same protections while eliminating the cost, overhead and complexity the SEG introduces to their business.

These protections differs in many ways from traditional legacy protections and include the ability to secure sending domains through DMARC email authentication, continuously protect against evolving identity-based attacks, automate remediation workflows for phishing incidents, and guard against email account takeover-based attacks.

This new paradigm of email security reduces the dependence on phishing training to defend organizations against the costly and timeconsuming business disruption caused by modern attacks. It also simplifies the security infrastructure, reduces capital expenditures, and overhead while better equipping organizations to achieve the intended business benefits from their cloud deployment.
